# Ensemble Methods

- Construct a set of classifiers from the training data
- Predict class label of test records by combining the predictions made by multiple classifiers

# Why Ensemble Methods work?

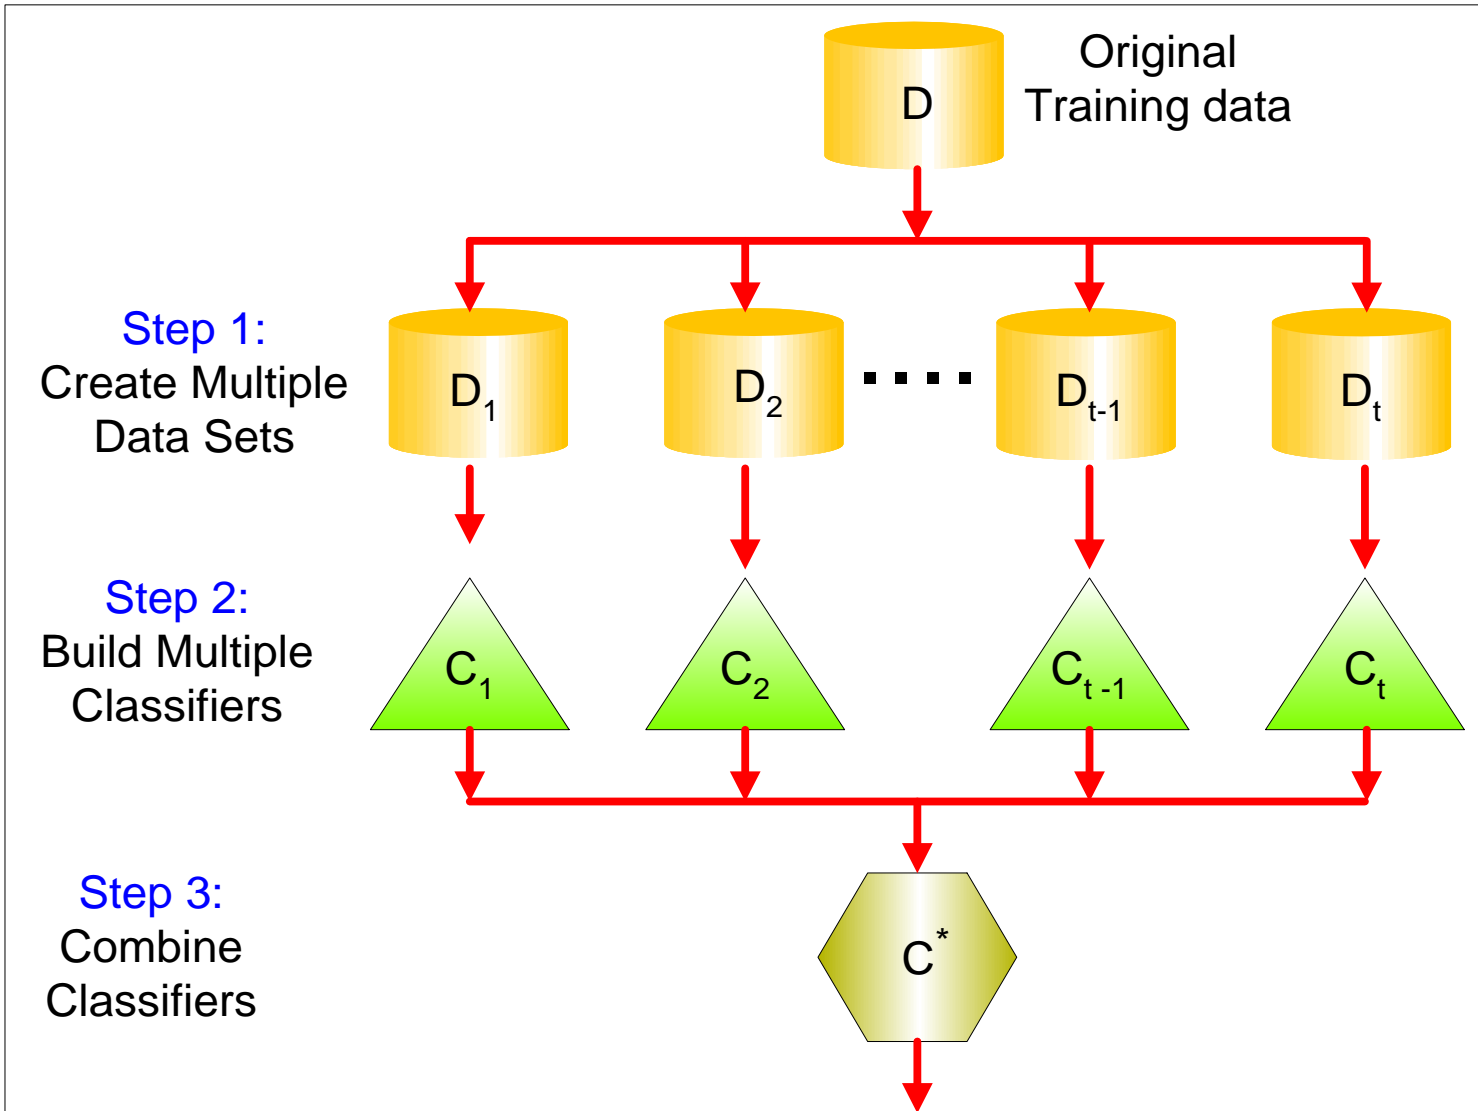

- Suppose there are 25 base classifiers
  - Each classifier has error rate,  $\varepsilon = 0.35$
  - Assume errors made by classifiers are uncorrelated
  - Probability that the ensemble classifier makes a wrong prediction:

$$P(X \geq 13) = \sum_{i=13}^{25} \binom{25}{i} \varepsilon^i (1 - \varepsilon)^{25-i} = 0.06$$

# General Approach

# Types of Ensemble Methods

- Manipulate data distribution
  - Example: bagging, boosting
- Manipulate input features
  - Example: random forests
- Manipulate class labels
  - Example: error-correcting output coding

# Boosting

- An iterative procedure to adaptively change distribution of training data by focusing more on previously misclassified records
  - Initially, all  $N$  records are assigned equal weights
  - Unlike bagging, weights may change at the end of each boosting round

# Boosting

- Records that are wrongly classified will have their weights increased
- Records that are classified correctly will have their weights decreased

Original Data	1	2	3	4	5	6	7	8	9	10
Boosting (Round 1)	7	3	2	8	7	9	4	10	6	3
Boosting (Round 2)	5	4	9	4	2	5	1	7	4	2
Boosting (Round 3)	4	4	8	10	4	5	4	6	3	4

- Example 4 is hard to classify
- Its weight is increased, therefore it is more likely to be chosen again in subsequent rounds

# AdaBoost

- Base classifiers:  $C_1, C_2, \dots, C_T$

- Error rate:

$$\varepsilon_i = \frac{1}{N} \sum_{j=1}^N w_j \delta(C_i(x_j) \neq y_j)$$

- Importance of a classifier:

$$\alpha_i = \frac{1}{2} \ln \left( \frac{1 - \varepsilon_i}{\varepsilon_i} \right)$$

# AdaBoost Algorithm

- Weight update:

$$w_i^{(j+1)} = \frac{w_i^{(j)}}{Z_j} \begin{cases} \exp^{-\alpha_j} & \text{if } C_j(x_i) = y_i \\ \exp^{\alpha_j} & \text{if } C_j(x_i) \neq y_i \end{cases}$$

where  $Z_j$  is the normalization factor

- If any intermediate rounds produce error rate higher than 50%, the weights are reverted back to  $1/n$  and the resampling procedure is repeated
- Classification:

$$C^*(x) = \arg \max_y \sum_{j=1}^T \alpha_j \delta(C_j(x) = y)$$

# AdaBoost Algorithm

---

## Algorithm 5.7 AdaBoost Algorithm

---

- 1:  $w = \{w_j = 1/n \mid j = 1, 2, \dots, n\}$ .    {Initialize the weights for all  $n$  instances.}
  - 2: Let  $k$  be the number of boosting rounds.
  - 3: for  $i = 1$  to  $k$  do
  - 4:    Create training set  $D_i$  by sampling (with replacement) from  $D$  according to  $w$ .
  - 5:    Train a base classifier  $C_i$  on  $D_i$ .
  - 6:    Apply  $C_i$  to all instances in the original training set,  $D$ .
  - 7:     $\epsilon_i = \frac{1}{n} [\sum_j w_j \delta(C_i(x_j) \neq y_j)]$     {Calculate the weighted error}
  - 8:    if  $\epsilon_i > 0.5$  then
  - 9:      $w = \{w_j = 1/n \mid j = 1, 2, \dots, n\}$ .    {Reset the weights for all  $n$  instances.}
  - 10:    Go back to Step 4.
  - 11:    end if
  - 12:     $\alpha_i = \frac{1}{2} \ln \frac{1-\epsilon_i}{\epsilon_i}$ .
  - 13:    Update the weight of each instance according to equation (5.88).
  - 14: end for
  - 15:  $C^*(\mathbf{x}) = \arg \max_y \sum_{j=1}^T \alpha_j \delta(C_j(\mathbf{x}) = y)$ .
-

# AdaBoost Example

- Consider 1-dimensional data set:

Original Data:

x	0.1	0.2	0.3	0.4	0.5	0.6	0.7	0.8	0.9	1
y	1	1	1	-1	-1	-1	-1	1	1	1

- Classifier is a decision stump
  - Decision rule:  $x \leq k$  versus  $x > k$
  - Split point  $k$  is chosen based on entropy

# AdaBoost Example

- Training sets for the first 3 boosting rounds:

Boosting Round 1:

<b>x</b>	0.1	0.4	0.5	0.6	0.6	0.7	0.7	0.7	0.8	1
<b>y</b>	1	-1	-1	-1	-1	-1	-1	-1	1	1

Boosting Round 2:

<b>x</b>	0.1	0.1	0.2	0.2	0.2	0.2	0.3	0.3	0.3	0.3
<b>y</b>	1	1	1	1	1	1	1	1	1	1

Boosting Round 3:

<b>x</b>	0.2	0.2	0.4	0.4	0.4	0.4	0.5	0.6	0.6	0.7
<b>y</b>	1	1	-1	-1	-1	-1	-1	-1	-1	-1

- Summary:

Round	Split Point	Left Class	Right Class	alpha
1	0.75	-1	1	1.738
2	0.05	1	1	2.7784
3	0.3	1	-1	4.1195

# Random Forest

---

## Algorithm 1 Random Forest

---

**Precondition:** A training set  $S := (x_1, y_1), \dots, (x_n, y_n)$ , features  $F$ , and number of trees in forest  $B$ .

```
1 function RANDOMFOREST( $S, F$ )
2    $H \leftarrow \emptyset$ 
3   for  $i \in 1, \dots, B$  do
4      $S^{(i)} \leftarrow$  A bootstrap sample from  $S$ 
5      $h_i \leftarrow$  RANDOMIZEDTREELEARN( $S^{(i)}, F$ )
6      $H \leftarrow H \cup \{h_i\}$ 
7   end for
8   return  $H$ 
9 end function
10 function RANDOMIZEDTREELEARN( $S, F$ )
11   At each node:
12      $f \leftarrow$  very small subset of  $F$ 
13     Split on best feature in  $f$ 
14   return The learned tree
15 end function
```

---

# Why Do Random Forests Work?

- Bagging can reduce the variance
- Advantages of choosing features from random subsets
  - Individual decision trees learnt from random feature sets are more uncorrelated
  - More decision trees can be learnt in a given amount of time due to small scale of features
- More details can be referred to
  - Breiman, Leo. "Random forests." *Machine learning* 45.1 (2001): 5-32.
